

STEM-REGULATED, PLANT DEFENSE PROMOTER AND USES THEREOF IN
TISSUE-SPECIFIC EXPRESSION IN MONOCOTS

PRIORITY CLAIM

5 The present invention claims priority under 35 U.S.C.
§119(e) to U.S. Provisional Pat. Appln. Ser. No. 60/437,974
filed on January 3, 2003 and titled "Stem-Expressed
Promoter for Tissue-Specific Expression in Monocots".

10 FIELD OF THE INVENTION

 The present invention relates to the fields of plant
functional genomics, molecular biology and genetic
engineering, and specifically to selective regulation of
gene expression in plants. In particular, the present
15 invention relates to novel isolated nucleic acids having
promoters capable of conferring stem-regulated expression
and operable in plant defense. The promoters may be used
in monocots, including polyploid species, to direct stem-
regulated or defense-inducible expression of a heterologous
20 gene.

BACKGROUND

A critical component of agriculture biotechnology is the use of highly regulated promoters to express agronomically important genes in crop plants so that genes
5 of interest are expressed at optimal levels in appropriate tissues.

Monocots form a substantial portion of the world's food supply. Sugarcane is considered as one of the major worldwide crop for sugar supply with a net value of \$20
10 billion per year. This crop could benefit from biotechnology approaches to engineer plants for disease, pest and herbicide resistance as well as improved sugar yield. However, compared to other major crops, there has been little research in developing sugarcane specific
15 technologies such as genes and promoters that are functional in sugarcane. At the present time, there are no public-domain sugarcane promoters available for use in sugarcane transformation.

The selection of a promoter is often a critical factor
20 in determining when and where within the plant the gene of interest is expressed.

A number of gene promoters that drive high levels of constitutive transgene expression are available for monocot plants. These include the maize ubiquitin promoter (Quail
25 et al., 1996, U.S. Patent No. 5,510,474), the rice actin1 promoter (McElroy and Wu, 1997, U.S. Patent No. 5,641,876), various enhanced cauliflower mosaic virus (CaMV) 35S promoters (Mitsuhara et al., 1996, Plant Cell Physiol.

37:49-59) and promoters isolated from banana streak virus (Schenk et al., 2001, Plant Mol. Biol. 47:399-412).

Promoters that have been isolated so far from sugarcane correspond to two polyubiquitin genes and confer

5 constitutive gene expression in non-host plants such as rice (Wei et al., 1999, J. Plant Physiol. 155:513-519; Wei et al., 2003, J. Plant Physiol. 160:1241-1251).

Constitutive promoters may be suitable for the production of a desired protein in large quantities in all
10 tissues of the plant throughout development. The energy requirements for high level constitutive production of the protein are often so great that other normal plant growth processes are compromised. For example, expression of a protein in a non-tissue specific manner as directed by a
15 constitutively active promoter has often resulted in slow-growing or dwarfed plants. Even though providing constitutive expression of a gene is often desirable, it is also desirable in many instances to direct high expression of a gene to particular tissues and/or time of development
20 in a plant. Tissue-specific promoters are capable of selectively expressing an introduced gene in desired tissues. Tissue-specific promoters may also be inducible, e.g. activated by internal or external agents such as phytohormones or defense inducing agents.

25 Restricting expression of the target protein to a particular tissue or organ or to specific events triggered when the plant is challenged with an external agent may be desirable to minimize possible toxic effects of some

'agronomic' gene products and to optimize overall plant growth and production. Furthermore, it is increasingly clear that promoter function varies from species to species. Thus it is essential to have promoters which are
5 expressed specifically in target tissues of specific plants in order to genetically engineer plants.

Several promoters are currently being used for tissue-specific, heterologous gene expression in monocots. For example, the promoter regions from genes coding for
10 hydrolases (β -glucanase), cysteine protease inhibitors (cystatin-1) or glucosidases (α -glucosidase) have been used to direct germination-specific expression of a heterologous DNA sequence in transgenic barley cells and kernels (Wolf, 1992, Mol. Gen. Genet. 234:33-42; Jensen et al., 1996,
15 Proc. Natl. Acad. Sci. USA 93:3487-3491; Mikkonen et al., 1996, Plant Mol. Biol. 31:239-254; Jensen et al., 1998, U.S. Patent No. 5, 712, 112; Lok et al., 2002, U.S. Patent No. 6,359,196). The promoter for the glutamine synthetase gene has been also used to drive tissue-specific expression
20 within the developing kernels of transgenic maize plants (Muhitch et al., 2002, Plant Science 163:865-872). Xylem- and phloem-specific promoters that are active in rice have also been reported, including the rice tungro baciliform virus and peroxidase gene promoters (Yin et al., 1997,
25 Plant Journal 12:1178-1188; Ito et al., 2000, Plant Science 155:85-100); however it is not clear whether these promoters are active in other monocots, such as maize, sorghum and sugarcane. Furthermore, none of the above

reported promoters are stem-regulated, which may be significant for crops such as sugarcane where the stem holds a large portion of the commercial value of the plant.

SUMMARY OF THE INVENTION

The present invention provides regulatory sequences which direct stem-regulated or defense-inducible expression and include novel promoters from stem-expressed defense-inducible gene designated jasmonate-induced protein (JAS).
5 The subject promoters may have specific advantages over the currently available tissue-specific promoters in their enhanced specificity in regulating gene expression in stem tissues and in response to induction by external stimuli
10 such as plant defense-inducing agents. The subject promoters may be very useful in strategies aimed at altering carbon metabolism in the sucrose accumulating tissues, and for driving expression of insecticidal proteins in sugarcane. These promoters may also be applied
15 to the development of improved pest and disease tolerant rice plants.

The present invention is directed to isolated nucleic acids including promoters operable primarily in the stem or in response to stimulation by defense-inducing agents. The
20 subject promoters hybridize under stringent conditions to a promoter isolated from sugarcane, designated the JAS promoter, which promoter has the nucleotide sequence as set forth in SEQ ID NO:1

In other embodiments of the invention, the subject
25 isolated nucleic acids include promoters which direct stem-regulated or defense-inducible expression and have a sequence identity (sequence similarity) of from about 60% to about 65%, from about 65% to about 75%, from about 75%

to about 85%, or from about 85% to about 90% when compared to the nucleotide sequence of the JAS promoter as set forth in SEQ ID NO: 1. Promoters of the present invention may also have a sequence identity of at least 60%, at least
5 70%, at least 80%, at least 90%, at least 95%, or at least 98% when compared to the JAS promoter of SEQ ID NO: 1. It will be understood by one skilled in the art that where the designation "JAS promoter" is used in the present specification, use of other nucleic acids having
10 hybridization characteristics or homologous sequences as set forth above may be appropriate as well unless a specific identity or sequence is clearly indicated. However, all JAS promoters retain some ability to direct stem-regulated transcription or defense-inducible
15 transcription.

In a further embodiment, the present invention is directed to an isolated nucleic acid having a promoter which directs stem-regulated or defense-inducible expression, which promoter has the nucleotide sequence as
20 set forth in SEQ ID NO:1.

Other embodiments of the invention include expression vectors including an isolated nucleic acid having a promoter which directs stem-regulated or defense-inducible expression, including an JAS promoter. The expression
25 vector may, more specifically, be transferred into a plant cell to be transformed in such a manner as to allow expression of an encoded protein in tissues derived from the plant cell. The vector may also transmitted into the

plant cell in such a manner as to allow inheritance of the nucleic acid into the second progeny of plants generated from a plant derived from the transformed plant cell. More specifically, such inheritance may be Mendelian. Examples
5 of plant transformation expression vectors including the JAS promoter are shown in FIGURES 2 and 3.

In still another embodiment, the present invention may be directed to cells, tissues and plants transformed with an expression vector including an isolated nucleic acid
10 having a promoter which directs stem-regulated or defense-inducible expression, including an JAS promoter, and the progeny generated from such transformed plants. In specific embodiments, the plant may be a monocot, such as maize, rice, sugarcane or sorghum.

15 In still further embodiments, the present invention provides an expression cassette which includes an isolated nucleic acid having a promoter which directs stem-regulated or defense-inducible expression including an JAS promoter operably linked to a heterologous gene or a nucleic acid
20 encoding a sequence complementary to the native plant gene and vectors containing such expression cassettes.

The present invention also includes methods for directing stem-regulated expression in a tissue or plant by providing such tissue or plant with an isolated nucleic
25 acid having a promoter including an JAS promoter to effect such stem-regulated expression. Other methods relate to directing defense-inducible expression in a plant by providing such plant with an isolated nucleic acid having a

promoter including an JAS promoter to effect such defense-inducible expression.

Finally, the invention includes methods of isolating a tissue-specific promoter in polyploid monocots by first
5 selecting potential tissue-specific cDNA clones using differential hybridization analysis followed by microarray analysis if the cDNA clones using probes derives from total RNA of various tissues. This may be followed by further confirmation techniques such as real time PCR and RNA gel
10 blot analysis using total RNA of various tissues.

BRIEF DESCRIPTION OF THE DRAWINGS

Specific embodiments of the present invention are further described in the following detailed description taken in conjunction with the accompanying drawings. The
5 file of the present patent contains at least one drawing executed in color as determined by the U.S. Pat. and Trademark Office. Copies of this patent with color drawing(s) will be provided by the Patent and Trademark Office upon request and payment of the necessary fees.

10 FIGURE 1 depicts, according to an embodiment of the present invention, the nucleotide sequence of a 2.686 kb fragment (SEQ ID NO:1) of the jasmonate-induced protein gene (JAS) which lies immediately upstream of the putative translational start site. The putative TATA box, CAT box
15 sequence and first ATG are bolded.

FIGURE 2 illustrates, according to an embodiment of the present invention, the JAS promoter/GUS expression vector (pJAS::GUSpUC19) suitable for expression in sugarcane, maize and sorghum.

25 has been used to drive expression of a GUS reporter protein.

DETAILED DESCRIPTION

The present invention includes isolated nucleic acids having promoters capable of directing specific expression in stem tissue or operable in response to stimulation by defense-inducing agents. In accordance with the present invention, a subject promoter, when operably linked to either the coding sequence of a gene or a sequence complementary to a native plant gene, directs expression of the coding sequence or complementary sequence in stem tissue or in response to a defense-inducing agent.

In one embodiment of the present invention, there is provided an isolated nucleic acid corresponding to a promoter isolated from a sugarcane stem-regulated, defense-inducible gene, designated jasmonate-induced protein (JAS) promoter, having the sequence of nucleotides -2686 to -1 as depicted in FIGURE 1 (SEQ ID NO:1).

The promoters of the present invention are useful in the construction of expression cassettes which include, in the 5' to 3' direction, a promoter which directs stem-regulated or defense-inducible expression such as the JAS promoter, a heterologous gene or a coding sequence, or sequence complementary to a native plant gene under control of the promoter, and a 3' termination sequence. Such an expression cassette may be incorporated into a variety of autonomously replicating vectors in order to construct an expression vector.

In one embodiment of the present invention, there is provided a promoter from a sugarcane JAS gene. An isolated

nucleic acid for a promoter from an JAS gene can be provided as follows. JAS recombinant genomic clones are first isolated by screening a sugarcane genomic bacterial artificial chromosome (BAC) library with a cDNA (or a
5 portion thereof) representing JAS mRNA. In order to obtain a cDNA representing JAS mRNA, a sugarcane stem-regulated cDNA library may be constructed and screened by differential hybridization with stem, leaf and root cDNA probes to identify stem-regulated cDNAs including the JAS
10 cDNA.

Methods considered useful in obtaining genomic recombinant DNA sequences corresponding to the JAS gene by screening a genomic library are provided in Sambrook et al. (1989), Molecular Cloning: A Laboratory Manual, Cold Spring
15 Harbor, N.Y., for example, or any of the laboratory manuals on recombinant DNA technology that are widely available.

To determine nucleotide sequences, a multitude of techniques are available and known to the ordinarily skilled artisan. For example, restriction fragments
20 containing a corresponding JAS gene may be subcloned into the polylinker site of a sequencing vector such as pBluescript (Stratagene). These pBluescript subclones may then be sequenced by the double-stranded dideoxy method (Chen et al. (1985) DNA, 4; 165).

25 In a specific embodiment of the present invention, the JAS promoter includes nucleotides -2686 to -1 of FIGURE 1 (SEQ ID NO:1).

Modifications to the JAS promoter as set forth in SEQ ID NO:1, which maintain the characteristic property of directing stem-regulated or defense-inducible expression, are within the scope of the present invention. Such
5 modifications include insertions, deletions and substitutions of one or more nucleotides.

The subject JAS promoter may be derived from restriction endonuclease or exonuclease digestion of isolated JAS genomic clones. Thus, for example, the known
10 nucleotide or amino acid sequence of the coding region of a gene of the jasmonate-induced protein gene family is aligned to the nucleic acid or deduced amino acid sequence of an isolated stem-regulated genomic clone and the 5' flanking sequence (i.e., sequence upstream from the
15 translational start codon of the coding region) of the isolated JAS genomic clone is located.

The JAS promoter as set forth in SEQ ID NO:1 (nucleotides -2686 to -1 of FIGURE 1) may be generated from genomic clones having either or both excess 5' flanking sequence or coding sequence by exonuclease III-mediated deletion. This is accomplished by digesting
20 appropriately prepared DNA with exonuclease III (exoIII) and removing aliquots at increasing intervals of time during the digestion. The resulting successively smaller
25 fragments of DNA may be sequenced to determine the exact endpoint of the deletions. There are several commercially available systems which use exonuclease III (exoIII) to create such a deletion series, e.g. Promega Biotech,

"Erase-A-Base®" system. Alternatively, PCR primers may be defined to allow direct amplification of the subject JAS promoter.

5 Using the same methodologies, the ordinarily skilled artisan may generate one or more deletion fragments of the JAS promoter as set forth in SEQ ID NO:1. Any and all deletion fragments which include a contiguous portion of the nucleotide sequences set forth in SEQ ID NO:1 and which retain the capacity to direct stem-regulated or defense-
10 inducible expression are contemplated by the present invention.

In addition to the sugarcane JAS promoter having the nucleotide sequence set forth as -2686 to -1 in FIGURE 1 (SEQ ID NO:1), the present invention is directed to other
15 promoter sequences which correspond to the same gene, i.e., a homolog, in other plant species. As defined herein, such related sequences which direct stem-regulated or defense-inducible expression, may be described in terms of their percent homology or identity on a nucleotide level to the
20 nucleotide sequence (-2686 to -1) as set forth in FIGURE 1 (SEQ ID NO:1). Alternatively, such related sequences from other plant species may be defined in terms of their ability to hybridize to the JAS promoter of SEQ ID NO: 1 under stringent hybridization conditions.

25 The present invention therefore contemplates nucleic acid sequences hybridizing with the JAS nucleic acid sequence as set forth in FIGURE 1 (SEQ ID NO:1) and which differ in one or more positions in comparison with SEQ ID

NO:1 so long as such hybridizing sequence corresponds to a promoter which directs stem-regulated or defense-inducible expression.

By "hybridizing" it is meant that such nucleic acid
5 molecules hybridize under conventional hybridization conditions, preferably under stringent conditions such as described by, e.g., Sambrook (Molecular Cloning; A Laboratory Manual, 2nd Edition, Cold Spring Harbor Laboratory Press, Cold Spring Harbor, N.Y. (1989)). An
10 example of one such stringent hybridization condition is hybridization in 4 x SSC at 65°C, followed by a washing in 0.1 x SSC at 65°C for one hour. Alternatively, an exemplary stringent hybridization condition is in 50% formamide, 4 x SSC at 42°C.

15 Promoter sequences of the present invention may also be described in terms of percent homology or identity on a nucleotide level to the nucleotide sequence -2686 to -1 depicted in FIGURE 1 (SEQ ID NO:1). There are a number of computer programs that compare and align nucleic acid
20 sequences which one skilled in the art may use for purposes of determining sequence identity (sequence similarity).

Thus, an isolated nucleic acid is provided having a promoter which directs stem-regulated or defense-inducible expression has a sequence identity (sequence similarity) of
25 about 60% to about 65% when compared to the nucleotide sequence of the JAS promoter as set forth in SEQ ID NO:1. In a specific embodiment, an isolated nucleic acid including a promoter which directs stem-regulated

expression has a sequence identity (sequence similarity) of about 65% to about 75% when compared to the sequence of the JAS promoter as set forth in SEQ ID NO:1.

5 In another specific embodiment, an isolated nucleic acid including a promoter which directs stem-regulated expression has a sequence identity (sequence similarity) of about 75% to about 85% when compared to the sequence of the JAS promoter as set forth in SEQ ID NO:1.

10 In another specific embodiment, an isolated nucleic acid including a promoter which directs stem-regulated expression has a sequence identity (sequence similarity) of about 85% to about 90% when compared to the sequence of the JAS promoter as set forth in SEQ ID NO:1.

15 In another specific embodiment, an isolated nucleic acid including a promoter which directs stem-regulated expression has a sequence identity (sequence similarity) of about 90% or greater when compared to the sequence of the JAS promoter as set forth in SEQ ID NO:1.

20 Sequences similar to a subject promoter may be identified by database searches using the promoter or elements thereof as the query sequence using the Gapped BLAST algorithm (Altschul et al., 1997 Nucl. Acids Res. 25:3389-3402) with the BLOSUM62 Matrix, a gap cost of 11 and persistence cost of 1 per residue and an E value of 10.
25 Two sequences may be compared with either ALIGN (Global alignment) or LALIGN (Local homology alignment) in the FASTA suite of applications (Pearson and Lipman, 1988 Proc. Nat. Acad. Sci. 85:2444-24448; Pearson, 1990 Methods in

Enzymology 183:63-98) with the BLOSUM50 matrix and gap penalties of -16, -4.

Nucleic acid molecules corresponding to promoters of the present invention may be obtained by using the subject
5 2,686 kb JAS promoter of SEQ ID NO: 1 or a portion thereof (including fragments) or complements thereof as a probe and hybridizing with a nucleic acid molecule(s) from any higher plant. Nucleic acid molecules hybridizing to the 3.012 kb JAS promoter or a portion thereof can be isolated, e.g.,
10 from genomic libraries by techniques well known in the art. Promoter fragments homologous to JAS may also be isolated by applying a nucleic acid amplification technique such as the polymerase chain reaction (PCR) using as primers oligonucleotides derived from sequence set forth in SEQ ID
15 NO:1.

Confirmation of the stem-specificity or defense-inducibility of the JAS promoter (including modifications or deletion fragments thereof), and promoters from homologous genes which direct stem-regulated or defense-
20 inducible expression, may be accomplished by construction of transcriptional and/or translational fusions of specific sequences with the coding sequences of a heterologous gene or coding sequence, transfer of the expression cassette into an appropriate host, and detection of the expression
25 of the heterologous gene or coding sequence. The assay used to detect expression depends upon the nature of the heterologous gene or coding sequence. For example, reporter genes, exemplified by chloramphenicol acetyl

transferase and β -glucuronidase (GUS), are commonly used to assess transcriptional and translational competence of chimeric nucleic acids. Standard assays are available to sensitively detect the reporter enzyme in a transgenic
5 organism.

The GUS gene is useful as a reporter of promoter activity in transgenic plants because of the high stability of the enzyme in plant cells, the lack of intrinsic GUS activity in higher plants and availability of a
10 quantitative fluorimetric assay and a histochemical localization technique. Jefferson et al. (1987) (EMBO J. 6: 3901-3907) have established standard procedures for biochemical and histochemical detection of GUS activity in plant tissues. Biochemical assays are performed by mixing
15 plant tissue lysates with 4-methylumbelliferyl- β -D-glucuronide, a fluorimetric substrate for GUS, incubating one hour at 37°C, and then measuring the fluorescence of the resulting 4-methyl-umbelliferone. Histochemical localization for GUS activity is determined by incubating
20 plant tissue samples in 5-bromo-4-chloro-3-indolyl-glucuronide (X-Gluc) for about 18 hours at 37°C and observing the staining pattern of X-Gluc. The construction of such expression cassettes allows definition of specific regulatory sequences and demonstrates that these sequences
25 can direct expression of heterologous genes, or coding sequences in a stem-regulated or defense-inducible manner.

Another aspect of the invention is directed to expression cassettes and expression vectors including a

promoter which directs stem-regulated or defense-inducible expression such as an JAS promoter or portion thereof, operably linked to the coding sequence of a heterologous gene such that the regulatory element is capable of
5 controlling expression of the product encoded by the heterologous gene. The heterologous gene can be any gene other than JAS. If necessary, additional regulatory elements from genes other than JAS or parts of such elements sufficient to cause expression resulting in
10 production of an effective amount of the polypeptide encoded by the heterologous gene may be included in the expression cassettes.

As used herein, the term "cassette" refers to a nucleotide sequence capable of expressing a particular
15 coding sequence if said coding sequence is inserted so as to be operably linked to one or more regulatory regions present in the nucleotide sequence. Thus, for example, the expression cassette may include a heterologous coding sequence which is desired to be expressed in a plant seed.
20 The expression cassettes and expression vectors of the present invention are therefore useful for directing stem-regulated or defense-inducible expression of any number of heterologous genes.

Accordingly, the present invention provides expression
25 cassettes including sequences of a promoter which directs stem-regulated or defense-inducible expression including the JAS promoter which are operably linked to a heterologous gene such as a sugar transport gene or sugar

accumulation gene. Examples of sugar transport genes useful for practicing the present invention include sucrose transporters and other monosaccharide and disaccharide transporters. Such sugar transporter genes have been
5 isolated and characterized from sugarcane and other plant species. Their nucleotide coding sequences as well as methods of isolating such coding sequences are disclosed in the published literature and are widely available to those of skill in the art.

10 Additionally, the present invention includes expression cassettes which express products having an insecticidal or antimicrobial activity. Introduction into a plant cell of a expression cassette including an insecticidal or antimicrobial gene operably linked to the
15 subject promoter sequences such as the JAS promoter allows for protection in the stem. Examples of antimicrobial genes useful for practicing the present invention include chitinase and β -1,3-glucanase genes (Jach et al. 1995 Plant Journal 8:97-109). Expression cassettes which include the
20 subject promoter such as the JAS promoter operably linked to a bioinsecticidal peptide or a defence elicitor peptide that upregulate the endogenous pathway are particularly contemplated to amplify natural defense responses.

The expression cassettes of the present invention may
25 be constructed by ligating a subject promoter such as the JAS promoter or part thereof to the coding sequence of a heterologous gene. The juxtaposition of these sequences may be accomplished in a variety of ways. In one

embodiment, the sequence order is in a 5' to 3' direction and includes an JAS promoter and coding sequence of a heterologous gene. In another the sequence order in a 5' to 3' direction is an JAS promoter, a coding sequence and a
5 termination sequence which includes a polyadenylation site.

Standard techniques for construction of such expression cassettes are well known to those of ordinary skill in the art and can be found in references such as Sambrook et al. (1989). A variety of strategies are
10 available for ligating fragments of DNA, the choice of which depends on the nature of the termini of the DNA fragments.

The restriction or deletion fragments that contain a subject promoter TATA box are ligated in a forward
15 orientation to a promoterless heterologous gene or coding sequence such as the coding sequence of GUS. The skilled artisan will recognize that promoters of the present invention and parts thereof, may be provided by other means, for example chemical or enzymatic synthesis.

20 The 3' end of a heterologous coding sequence is optionally ligated to a termination sequence including a polyadenylation site, exemplified by, but not limited to, the nopaline synthase polyadenylation site, or the octopine T-DNA gene 7 polyadenylation site. Alternatively, the
25 polyadenylation site may be provided by the heterologous gene or coding sequence.

The present invention also provides methods of increasing expression levels of heterologous genes or

coding sequences in plant stem tissues. In accordance with such methods, the expression cassettes and expression vectors of the present invention may be introduced into a plant in order to effect expression of a heterologous gene or coding sequence. For example, a method of producing a plant with increased levels of a product of a sucrose accumulating gene or a defense gene is provided by transforming a plant cell with an expression vector including an JAS promoter or portion thereof, operably linked to a sucrose accumulating gene or a defense gene and regenerating a plant with increased levels of the product of the sucrose accumulating gene or defense gene. In a specific embodiment of the present invention, a transgenic sugarcane line may be produced in which the sugar metabolism is altered to increase its stem dry weight. This is of particular importance because commercial sugarcane varieties accumulate up to 50-60% of dry weight of their stem tissues as sucrose. In a further specific embodiment of the present invention, a transgenic sugarcane line may be produced with enhanced bioinsecticidal activity for protection against stem boring insects, which are the most destructive pests. Expression of the bioinsecticidal protein may be induced in this case by the application of a defense inducing agent such jasmonic acid.

Another aspect of the present invention provides methods of reducing levels of a product of a gene which is native to a plant which includes transforming a plant cell with an expression vector having an JAS promoter or part thereof, operably linked to a nucleic acid sequence which

is complementary to the native plant gene. In this manner, levels of endogenous product of the native plant gene are reduced through a mechanism known as antisense regulation. Thus, for example, levels of a product of a sucrose
5 accumulating gene or defense gene are reduced by transforming a plant with an expression vector including an JAS promoter or part thereof, operably linked to a nucleic acid sequence which is complementary to a nucleic acid sequence coding for a native sucrose accumulating gene or a
10 defense gene.

The present invention also provides a method of silencing a gene native to a plant which includes transforming a plant cell with an RNA interference (RNAi) expression vector including an JAS promoter or part
15 thereof, operably linked to a nucleic acid sequence which is an inverted repeat of the native plant gene. In this manner, levels of endogenous product of the native plant gene are reduced through a mechanism known as RNA interference. Thus, for example, levels of a product of a
20 sucrose synthesis gene may be reduced by transforming a plant with an expression vector including a subject stem-regulated promoter or part thereof, operably linked to a nucleic acid sequence which is an inverted repeat of the nucleic acid sequence coding for a native sucrose
25 accumulating gene or a defense gene.

The present invention further provides a method of cosuppressing a gene which is native to a plant which includes transforming a plant cell with an expression

vector having an JAS promoter or part thereof, operably linked to a nucleic acid sequence coding for the native plant gene. In this manner, levels of endogenous product of the native plant gene are reduced through the mechanism
5 known as cosuppression. Thus, for example, levels of a product of a sucrose synthesis gene or defense gene may be by transforming a plant with an expression vector including a subject promoter or part thereof, operably linked to a nucleic acid sequence coding for a sucrose accumulating
10 gene or defense gene native to the plant. Although the exact mechanism of cosuppression is not completely understood, one skilled in the art is familiar with published works reporting the experimental conditions and results associated with cosuppression (Napoli et al. (1990)
15 The Plant Cell, 2; 270-289; Van der Krol (1990) Plant Mol. Biol, 14; 457-466.)

To provide regulated expression of the heterologous or native genes, plants may be transformed with the expression cassette constructions of the invention. Methods of nucleic
20 acid transfer are well known in the art. The expression cassettes may be introduced into plants by leaf disk transformation-regeneration procedure as described by Horsch et al. (1985) Science, 227; 1229-1231. Other methods of transformation such as protoplast culture
25 (Horsch et al. (1984) Science, 223; 496; DeBlock et al. (1984) EMBO J., 2; 2143; Barton et al. (1983) Cell, 32; 1033) may also be used and are within the scope of this invention. In a specific embodiment, plants including rice and other monocots and dicots are transformed with

Agrobacterium-derived vectors such as the pCambia vectors described in Maliga et al. (1994) (Plant Mol. Biol., 35; 989-994) (FIGURE 3). In another specific embodiment, embryonic calli and plant organs are transformed by gene
5 gun particle bombardment with the expression vector shown in FIGURE 2.

In another specific embodiment, stem tissues and embryonic calli are particle bombarded using the gene gun/biolistic approach as described in (Klein et al. (1987)
10 Nature, 327; 70). Other well-known methods are available to insert the expression cassettes of the present invention into plant cells. Such alternative methods include electroporation, chemically-induced DNA uptake, and use of viruses or pollen as vectors.

15 When necessary for the transformation method, the expression cassettes of the present invention may be inserted into a plant transformation vector, e.g. the binary vector described by Maliga et al. (1994) Plant Mol. Biol., 25; 989-994. Plant transformation vectors may be
20 derived by modifying the natural gene transfer system of Agrobacterium tumefaciens. The natural system comprises large Ti (tumor-inducing)-plasmids containing a large segment, known as T-DNA, which is transferred to transformed plants. Another segment of the Ti plasmid, the
25 vir region, is responsible for T-DNA transfer. The T-DNA region is bordered by terminal repeats. In the modified binary vectors, the tumor inducing genes have been deleted and the functions of the vir region are utilized to

transfer foreign DNA bordered by the T-DNA border sequences. The T-region also contains a selectable marker for antibiotic resistance, and a multiple cloning site for inserting sequences for transfer. Such engineered strains
5 are known as "disarmed" *A. tumefaciens* strains, and allow the efficient transfer of sequences bordered by the T-region into the nuclear genome of plants.

Embryonic calli and other susceptible tissues are inoculated with the "disarmed" foreign DNA-containing *A.*
10 *tumefaciens*, cultured for a number of days, and then transferred to antibiotic-containing medium. Transformed shoots are then selected after rooting in medium containing the appropriate antibiotic, and transferred to soil. Transgenic plants are pollinated and seeds from these
15 plants are collected and grown on antibiotic medium.

Expression of a heterologous or reporter gene in tissues, developing seeds, young seedlings and mature plants may be monitored by immunological, histochemical, mRNA expression or activity assays. As discussed herein,
20 the choice of an assay for expression of the expression cassette depends upon the nature of the heterologous coding sequence. For example, RNA gel blot analysis may be used to assess transcription if appropriate nucleotide probes are available. If antibodies to the polypeptide encoded by
25 the heterologous gene are available, Western analysis and immunohistochemical localization may be used to assess the production and localization of the polypeptide. Depending

upon the heterologous gene, appropriate biochemical assays may be used.

Another aspect of the present invention provides transgenic plants or progeny of these plants containing the expression cassettes of the invention. Both monocot and dicot plants are contemplated. Plant cells may be transformed with the expression cassettes by any of the plant transformation methods described above. The transformed plant cell, usually in the form of a callus culture, leaf disk, explant or whole plant (via *Agrobacterium*-mediated transformation or gene gun particle bombardment) may be regenerated into a complete transgenic plant by methods well-known to one of ordinary skill in the art (e.g., Horsh et al., 1985). In a specific embodiment, the transgenic plant is sugarcane, rice, maize, sorghum or other monocot plant. Because progeny of transformed plants inherit the expression cassettes, seeds or cuttings from the transformed plants may be used to maintain the transgenic line.

Finally, the invention includes methods of isolating a tissue-specific promoter in polyploid monocots by first selecting potential tissue-specific cDNA clones using differential hybridization analysis followed by microarray analysis if the cDNA clones using probes derived from total RNA of various tissues of interest. Differential hybridization use cDNA probes specific to tissue of interest. These tissues of interest may be selected to include not only a tissue in which expression is desired,

but also other tissues in which expression is not desired.
This provides additional screening criteria.

This may be followed by further confirmation
techniques such as real time PCR and RNA gel blot analysis
5 using total RNA of various tissues. Finally, because
promoter/PCR walking is difficult in polyploid plants, the
promoter may have to be isolated by screening a
bacteriophage library. If promoters thus located contain
internal restriction sites that prevent removal from phage
10 clones, genomic walking may be used to isolate the
promoter.

EXAMPLES

The invention may be further understood through reference to the following examples, which provide further description of specific embodiments of the invention.

- 5 Variations of these examples will be apparent to one skilled in the art and are intended to be encompassed in the present invention.

Example 1: Identification of Stem-Specific cDNAs

10 *Stem-Specific cDNA Macroarray Analysis*

To identify cDNAs that were expressed in sugarcane stems, a cDNA library representing stem mRNA was constructed and screened by differential hybridization.

- 15 In order to have a cDNA library that has a good representation of mRNA from all regions of the stem, mRNA was separately isolated from top, mid and bottom portions of the stem of *Saccharum* spp. cultivar CP72-1210 and a pooled sample was used for preparation of the cDNA. Total RNAs and poly(A)⁺ RNAs were prepared using the RNeasy kit
20 and Oligotex kit from Qiagen, respectively. For the synthesis of cDNAs, the SMART PCR cDNA library construction kit (BDBiosciences Clontech) was selected since this technology utilizes a unique SMART oligonucleotide (cap finder) in the first strand cDNA synthesis followed by a
25 long distance PCR (LD PCR) amplification to generate high yields of full-length ds cDNAs. A pooled sample consisting of 100 ng of each of stem top, mid and bottom poly(A)⁺ RNAs was used for the preparation of first strand cDNAs which

were then selected to synthesize ds cDNAs by LD PCR. The sizes of ds cDNA ranged from 300 bp to 6 kb. To eliminate small and partial (less than full-length) cDNAs, the ds cDNA sample was subjected to gel fractionation and the agarose gel slice containing 500 bp to 3 kb was excised and purified. This selected cDNA fraction was cloned into pCR2.1 vector (TA cloning kit, Invitrogen) using DH10B Escherichia coli bacterial cells for transformation. The ampicillin-resistant and white colonies were picked and archived in 384-well microtiter plates. A total of 13,824 cDNA clones (archived in thirty six 384-well microtiter plates) were obtained. About 100 clones were randomly picked, and DNA preparations were made and tested by restriction analysis to reveal insert sizes of 300 bp to 1500 bp.

Next the cDNA library was screened using differential hybridization to identify stem-specific cDNAs. Specifically, macroarrays consisting high density replica filters (three copies: A, B and C) of the library were prepared using a 3X3 duplicate grid pattern using a Beckman Biomek 2000. Each copy of the library (9 filters) was first probed with radioactively-labeled (random decamer priming method; Decaprime II kit, Ambion) cDNA of top, mid and bottom stem tissues, respectively. Hybridization were carried out at 65.degree.C. and blots were washed up to the final stringency of 0.3.times.SSC/0.1.percen.SDS and exposed to X-ray films. After the autorads from these hybridizations were obtained, filters of copies A and B were stripped and hybridized with 32P-labeled cDNA probes

of leaf and root tissues, respectively. Both strong and weak hybridization signals were recorded with an intention of identifying cDNAs that are strongly expressed in one type of tissue but weak in all others and vice versa.

5 Using this strategy, information from all possible combinations (stem top vs root, stem mid vs leaf, stem mid vs root, stem bottom vs leaf, stem bottom vs root, stem top vs stem mid, stem top vs stem bottom, stem mid vs stem bottom and leaf vs root) was gathered. Data obtained from
10 these substractions revealed that a total of 188 cDNAs were present specifically in stem and 41 cDNAs displayed constitutive expression. To further corroborate the expression patterns of these cDNA clones, DNA gel blots
15 clones and probed with radioactively-labeled cDNA from five tissues separately. Based on these analyses, 25 clones displayed stem-specific expression and 11 clones showed constitutive expression (See FIGURE 4).

20 *Stem-Specific cDNA Microarray Analysis*

The macroarray analysis of the potential stem-specific CAN clones was followed by a focused microarray analysis. A DNA microarray including the panel of the 188 stem-specific cDNA clones initially identified by the macroarray analysis
25 along with 63 additional cDNA clones was constructed to provide a sensitive assessment of their differential RNA expression profiles. Amplified PCR products for the 251 cDNAs were printed in duplicate on glass microscope slides

using a gridding robot from Genemachines. The resulting microarray was probed with fluorescently labeled cDNAs synthesized from 1.µg of total amplified RNA (MessageAmp aRNA kit from Ambion for RNA amplification). One cDNA
5 probe (e.g. stem RNA) is labeled with one dye (Cy5), and the second (e.g. leaf or root RNA) with another dye (Cy3) using the 3DNA Array 350RP expression array detection kit of Genisphere and based on the two-color fluorescent
10 hybridization microarray system developed by Brown and colleagues at Stanford (Derisi et al. 1996 Science 278:680-686). The two probes labeled with distinct dyes were hybridized simultaneously to a single DNA array to allow for comparison of two different RNA populations or internal standardization. Hybridization was detected and quantified
15 with a confocal laser scanner (Affymetrix) that captures the image of the emission wavelength of each dye. A combined image of the microarray hybridized with fluorescent probes representing stem RNA and leaf RNA is shown in FIGURE 5. The resulting digital data was analyzed
20 with the GenePix analysis software (Axon) and GeneSpring analysis software (Silicon Genetics). FIGURE 6 shows a scatter plot representation of the RNA expression levels of the 251 cDNA clones of the microarray after hybridization with probes from stem and leaf RNAs. Each '+' symbol
25 represents a cDNA. The normalized abundance of each cDNA derived from stem RNA (Cy5) (y axis) was plotted vs that derived from leaf RNA (Cy3) (x axis). Data were normalized using the endogenous constitutive gene ubiquitin. The central magenta line indicates equal hybridization of both

Cy5 and Cy3 probes. The outer magenta line indicates expression levels of genes that are two-fold up or down.

Among the 251 cDNAs examined in the microarray analysis, 41 appeared to be at least two-fold upregulated
5 in the stem, whereas 14 were constitutively expressed.

These 41 cDNAs were sequenced using cycle sequencing with an ABI PRISM dye terminator cycle sequencing kit. Database searches for homologous nucleic acids were performed through NCBI using the BLAST algorithm. Several
10 of the 41 stem-upregulated cDNA clones were found to belong to multigene families. One cDNA that exhibited a 3.2-fold upregulation shared significant sequence similarity to a monocot gene involved in defense pathways o-methyl transferase (OMT). In maize OMT is a key enzyme in the
15 biosynthetic pathway of phenolic compounds. It is induced by fungal pathogens and other stress conditions and functions in stress compensation and lignification (See Held, B.M. et al., *Plant Physiol.*, 102:1001-1008, 1993.)

The expression levels of other cDNAs were also found
20 to be two-fold upregulated. These include the cDNAs for jasmonate-induced protein (JAS). (See Lee, J. *Plants*, 199:625-632, 1999.) Other upregulated cDNA were found to correlate with additional genes, such as maize o-methyl transferase (OMT) gene and the salt stress-induced protein
25 gene (SSIP). Upregulation findings are presented in Table 1.

Table 1: Cy5/Cy3 Ratios (Upregulation) of Stem-regulated Genes in Microarray Analysis

Stem-Upregulated Genes	Normalized Cy5/Cy3 Ratios
JAS Clone 6H10	9.1
JAS Clone 20G16	4.7
JAS Clone 5P22	4.6
JAS Clone 20F18	3.6
JAS Clone 17C11	3.2
JAS Clone 403	3.1
JAS Clone 24G4	3.1
JAS Clone 10P7	3.0
JAS	3.2
SSIP	5.2
Protein translation factor SUI1 homolog	3.0

*Real-Time Quantitative RT-PCR Analysis of Gene Expression
in Stem*

The expression patterns of four selected cDNAs that were upregulated at least two-fold in the microarray analysis were further assessed by real-time quantitative PCR (RT-PCR). The four cDNAs include OMT, JAS clone 20F18, JAS clone 6H10 and SSIP. The real-time RT-PCR approach allows the identification of false positives obtained through the microarray analysis as well as the differentiation between members of multigene families.

Total RNA (2.µg) was extracted from sugarcane stem, leaf or root and the corresponding cDNA templates were generated through RT-PCR using the TaqMan reverse

transcription kit (Applied Biosystems). PCR was then performed using the cDNA templates and primers that are specific to the cDNAs of OMT, JAS, SSIP and ubiquitin (endogenous control). Primers were designed by the Primer Express software (Applied Biosystems) and labeled with the fluorescent SYBR Green 1 dye that binds to double-stranded DNA (SYBR Green PCR master mix; Applied Biosystems). The increase in fluorescence was measured for each PCR cycle with the ABI Prism 7700 Sequence Detection System (Applied Biosystems) since the incorporation of SYBR Green 1 dye into a real-time PCR reaction allows the detection of any double-stranded DNA generated during PCR. Real-time RT-PCR quantitations (Ct values) for the four cDNAs as normalized to the endogenous constitutive control ubiquitin are shown in FIGURE 7. These results demonstrate that OMT as well as SSIP and the two JAS clones are strongly expressed in stem as compared to leaf or root.

Quantitative RNA Gel Blot Analysis of Gene Expression in Stem

To further confirm actual upregulation of OMT in sugarcane stem, a quantitative RNA gel blot analysis was performed using total RNA (12.µg) from stem, leaf or root and radioactive probes specific to OMT, SSIP, JAS clone 20F18 and ubiquitin. Hybridization signals were recorded with a Fujix BAS 2000 phosphorimager. The data were analyzed using MacBas software. The hybridization signal for each sample was quantitated and adjusted for loading by virtue of hybridization to a ubiquitin cDNA probe. The

quantitative accumulation of OMT, JAS and SSIP was determined and compared to that of the constitutive ubiquitin gene (See FIGURE 8). All 3 cDNAs were highly expressed only in stem.

- 5 JAS upregulation as confirmed by the three analytical methods described above is summarized in Table 2.

Table 2: Upregulation of JAS and SSIP in Stem Tissue

Gene	Microarray fold increase (stem v. leaf)	RT-PCR fold change		RNA gel blot fold change	
		Stem v. leaf	Stem v. root	Stem v. leaf	Stem v. root
JAS	3.6	1.6	1.3	1.3	1.4
SSIP	5.2	1.0	1.0	4.5	5.7

10 **Example 2: Effects of Defense-Inducing Agents on OMT Upregulation**

The 251 cDNA clones used for microarray analysis in Example 1 were further used to assess the effects of defense-inducing agents on the expression of the stem-specific genes.

- 15 Total RNA was extracted from wild type sugarcane plants (3 months-old) that were sprayed with the defense-inducing agents jasmonic acid (JA) (25.mu.M in 0.05.percent.Tween 20), methyl-jasmonate (MeJA) (200.mu.M in 0.1.percent.ethanol and 0.05.percent.Tween 20) or 20 salicylic acid (SA) (5 mM in 0.05.percent.Tween 20) for two

time periods, 24 and 48 hours. The microarray including 251 cDNAs was probed with fluorescently labeled cDNAs synthesized from 1.µg of total amplified RNA. One cDNA probe (e.g. RNA from plant treated with a defense-inducing agent) is labeled with one dye (Cy5), and the second (e.g. RNA from untreated control plant) with another dye (Cy3)

Microarray data was analyzed using GeneSpring analysis software. Data were normalized using an endogenous constitutive gene. The normalized ratio of Cy5 v. Cy3 for JAS intensity after treatment with each defense-inducing agent is summarized in Table 3.

*Table 3: Cy5/Cy3 Ratios (Upregulation) for JAS
Following Treatment with Defense-Inducing Agents*

Clone	JA Treatment		MeJA Treatment		SA treatment
	24 hours	48 hours	24 hours	48 hours	48 hours
13F16	0.51	2.21	0.25	0.34	No data
6H10	0.42	2.19	0.15	0.19	19.22
17C11	0.35	2.12	0.17	0.17	18.83
4Q3	0.41	2.12	0.15	0.18	15.26
5P22	0.41	2.10	0.16	0.17	18.08
10P7	0.59	2.10	0.13	0.15	20.96
2I1	0.59	2.10	0.27	0.22	16.92
20F18	0.34	2.00	0.16	0.18	19.54
12F18	0.51	1.64	0.20	0.21	17.54
20G16	0.85	1.30	0.50	0.49	13.81
24G4	0.41	1.14	0.37	0.41	7.73
25K14	1.73	1.65	3.07	1.02	0.70
18H16	1.90	1.40	3.00	0.79	0.70

These results generally show that the JAS gene is
5 upregulated by approximately 48 hours after treatment with
a defense-inducing agent.

**Example 3: Isolation and Cloning of Genomic Sequence
Corresponding to JAS Gene and Promoter Release**

10 Initially, an attempt was made to use PCR walking to
clone the JAS promoter directly from genomic DNA. However,
the complexity of the sugarcane genome and the presence of

substantial amounts of repetitive DNA in it rendered this approach unworkable.

A second attempt to locate the JAS promoter was made using a sugarcane bacteriophage lambda (BAC) genomic
5 library. BAC library filters were probed using a full-length JAS cDNA probe. Three screening were performed to select genomic clones exhibiting strong hybridization to JAS cDNA. Phage DNA was isolated from 13 candidate JAS genomic clones and digested with restriction endonucleases
10 (EcoRI and HindIII) prior to DNA gel blot analysis. DNA gel blot analysis (shown in FIGURE 9) revealed common restriction fragments containing the JAS gene. This indicated that the 13 JAS clones were most likely representative of a single JAS locus.

15 However, the JAS promoter could not be directly released from any BAC clone because of the presence of several restriction fragments within each clone. Genomic walking was required to obtain the promoter. Using a Clontech Genome Walker kit, the JAS gene was amplified from
20 libraries. The general PCR-based approach is shown in FIGURE 10. FIGURE 11A shows a gel of the primary PCR products of the JAS BAC clone 159E16. PCR was conducted using an adapter primer and a 3' primer specific to the JAS 5' UTR. FIGURE 11B shows a gel blot of PCR products probed
25 using a JAS oligo specific to the 5'UTR of JAS.

The JAS promoter was thus identified and sequenced to reveal a 2.686 kb promoter fragment (See FIGURE 1 and SEQ ID NO:1.)

Example 4: Vector Construction and Expression In *Planta*

A sugarcane expression vector was produced by cloning either the JAS promoter into a pUC19 GUS reporter vector to
5 produce the pJAS::GUSpUC19 vector. (See FIGURE 2.)

Specifically, the 35S promoter normally found in pUC19 GUS was replaced with a JAS promoter at the corresponding XbaI and NcoI restriction sites to create a translational fusion with the GUS reporter DNA.

10 A rice expression vector was also produced by cloning the pJAS promoter into the plant binary expression vector pCambia 1301 to create pJAS::GUSpCambia. (See FIGURE 3.)
The 35S promoter normally pCambia 1301 was replaced at the corresponding XbaI and NcoI restriction sites to create a
15 translational fusion with the GUS reporter DNA.

Stable expression of GUS under control of the JAS promoter was achieved in sugarcane. Furthermore, such expression was stem-specific.

Specifically, embryonic calli of sugarcane cultivar
20 CP72-1210 were transformed with pOMT::GUSpUC vectors using gene gun/biolistic-mediated transfer (Irvine and Mirkov, 1997 Sugar Journal 60:25-29; Inglebrecht et al, 1999 Plant Physiol. 119:1187-1197). Histochemical localization of GUS expression was determined using 5-bromo-4-chloro-3-indoyl
25 glucuronide. (See FIGURE 12A.) Intense GUS staining was observed in the stem nodal area and vascular bundles. (See FIGURE 12B.)

Embryonic rice calli (Taipei 309) were transformed with pOMT:pUCpCambia using *Agrobacterium tumefaciens* EHA 105 (Aldemita and Hodges 1996). Histochemical analysis of transformed clones showed intense GUS staining in the stem
5 vascular bundles. (See FIGURE 13.)

Tissue analysis was used to confirm the presence of GUS in transformed plants. Expression as compared to that driven by maize *ubiquitin 1* was also studied. The results of this analysis are presented in Table 4.

10

Table 4: Evaluation of JAS Promoter Activity in Rice and Comparison to Ubiquitin 1 Promoter

	Tissue		
Line	Stem	Leaf	Root
Untransformed	0.19 ± 0.01	0.1 ± 0.001	0.44 ± 0.11
pJAS::GUS #4	540.51 ± 119.08	248.34 ± 16.39	253.67 ± 24.83
#6	10.28 ± 0.67	0.41 ± 0.02	2.31 ± 0.30
#8	21.29 ± 3.77	0.06 ± 0.03	12.5 ± 2.83
#23	551.13 ± 70.71	338 ± 21.36	320.01 ± 22.36
pUbi1::GUS #5	32.50 ± 1.38	1.51 ± 0.21	7.22 ± 0.28
#12	181.12 ± 30.40	1043.88 ± 142.25	1641.76 ± 98.16
#13	1418.22 ± 408.17	337.25 ± 88.43	158.60 ± 10.43

Values expressed are pmole 4-methylumbelliferyl β-D-glucuronide/μg total protein/minute. All assays were
15 performed in triplicate on 2 separate batches of samples.
